THE ORGANIZATION OF TUNA STATISTICS IN NEW ZEALAND

by

Carolyn Munro
Fisheries Research Division
Wellington, New Zealand

FOOD AND AGRICULTURE ORGANIZATION OF THE UNITED NATIONS
ROME, April 1986

PREPARATION OF THIS DOCUMENT

This paper was prepared as part of the background documentation for the Ad Hoc Consultation on Global Tuna Statistics, held in Colombo, Sri Lanka, 6-7 December 1985. It has been reproduced as a Fisheries Circular in view of its general interest as to how a small country without a long history of tuna fishing tackles the problems of collecting and processing statistical data.

W/R 9581

For bibliographic purposes this document should be cited as follows:

Munro, C., The organization of tuna statistics in New Zealand.
1986 FAO Fish.Circ., (795):21 p.

ABSTRACT

The New Zealand catch of tuna is slightly under 5,000 tons and that of foreign vessels in New Zealand waters rather more than 7,000 tons.* Possibilities for some growth in catches exist: Catch and effort data required for the management of these fisheries is collected by requiring New Zealand fishermen to furnish monthly, daily records of catch and effort by fishing area, and foreign fishermen to submit more detailed records of set position, environmental conditions and gear characteristics. Southern longline logbooks are returned when vessels clear New Zealand waters at the end of the season, Northern longline logbooks are returned from the home ports of the vessels. In addition to these routine records, special scientific investigations are made. Handling of the forms and summaries is made by staff with experience or knowledge of fishing, as they are better able to spot errors in the data. The data when checked and stored are available in different degrees of detail to different categories of user, with the more sensitive and detailed information available to specialist users.

* Errata. tons should read tonnes

THE ORGANIZATION OF TUNA STATISTICS IN NEW ZEALAND

I. Introduction

1. New Zealand waters support fisheries for three tuna species:- Skipjack (Katsuwonus pelamis), Southern bluefin (Thunnus maccoyii) and Albacore (t. alalunga). In addition, there is a significant by catch of Bigeye (T. obesus) and Yellowfin (T. albacares) with minor catches of Northern bluefin (T. thynnus) reported. These fisheries account for half of the catch in FAO Area 81 (Southwest Pacific), and further expansion of some of the tuna fisheries is envisaged. Table 1 shows the size of New Zealand fisheries by species, compared with the Southwest Pacific, total Pacific and world.

2. There are three domestic and two foreign tuna fisheries defined by area, method and target species. Two foreign longline fisheries operate, one to the north and a second to the southeast and east of New Zealand. The northern fishery targets on albacore, while the southern fishery targets on southern bluefin and bigeye tunas. A purse-seine fishery for skipjack that is primarily domestic concentrates on northern coastal waters over summer.

3. A domestic handline and troll fishery for large southern bluefin tuna operates from the west coast of the South Island during winter. The west coast of the South Island also supports an expanding troll fishery for albacore in summer months.

4. The national body mostly concerned with these fisheries is the Ministry of Agriculture and Fisheries (MAF), which has two divisions responsible for monitoring and managing all fisheries resources. Other groups interested in the industry rely on MAF for information and research. The agencies involved with or requiring regular information on New Zealand tuna fisheries are listed in Table 2.

II. Statistical Requirements

5. Tuna catch and effort data are gathered as part of the overall monitoring role of MAF. Management of foreign tuna fisheries is by limiting the number of vessels permitted to fish, and regulating the areas in which they can operate. Domestic fisheries have a quota for southern bluefin.

6. There are three levels of data which are routinely required: 1) data attributable to individual vessels; 2) detailed catch and effort summaries; and 3) summaries of annual landings.

7. The first category of information is required by MAF scientists who collect data on individual fishermen's daily activity (e.g. catch, effort, size of fish, area of operation, etc.). Individual catch, effort and vessel data are also required by Fisheries Officers for the purpose of law enforcement. Specific overseas research agencies also receive these data but with individual identity suppressed to maintain confidentiality.

8. Summaries of catch and effort by month, year, region, species and fishing method are routinely requested by fisheries managers and economists. These data summaries are also supplied on request to international agencies involved with the regional tuna fisheries. (e.g. UNDP/IPTP).

9. Data are also tabulated from the detailed summaries. These are available in publications and popular articles and are generally adequate to fulfil the requirements of fishermen, administrators, local bodies, researchers, politicians and commercial groups.

III. System for Collecting Statistics

10. There are two systems for collecting fisheries statistics. A national system provides long term catch and effort data for monitoring purposes and specific data are collected to supplement scientific programmes.

11. The Fisheries Statistics Unit (FSU) is the national body responsible for the collection and processing of fisheries statistics within the New Zealand EEZ. It comprises a staff of fourteen, based at the Fisheries Research Centre, Wellington. All fishermen are required by law to furnish information to the FSU on catch and effort and failure to file returns can result in prosecution. There is some variation in the detail required between fisheries. Domestic forms require a daily measure of catch and effort appropriate to specific fishing methods, and identification of the fishing area as one of the 52 domestic statistical areas. Foreign longline returns require considerably more detail on set position, environmental conditions and gear characteristics in order to provide a record of fishing patterns and of changes in fishing methods in fisheries where it is impractical to use observers. Examples of fishing returns processed by the FSU are included as Figures 1 to 5, while Table 3 provides a summary of these returns and the data derived from them.

12. Information is returned from the tuna fisheries monthly in the case of domestic fisheries and prior to the start of the following season in the case of foreign longline fisheries. Southern longline fishery logbooks are returned when vessels clear New Zealand ports at the end of each season. The northern longline vessels generally do not enter port during the season and logbooks are returned from their home ports, which in many instances imposes up to a two-year delay in receiving data.

13. The second system of statistical collection is run by MAF fisheries scientists and includes research logbooks completed by fishermen, observer programmes, and aerial sightings logbooks. These diverse data sources are used to give additional details on length, weight, and sex composition of the catch, logbook accuracy as well as information on school size and distribution. Table 4 describes the collection of these and of supplemental data while Figures 6 to 8 are examples of log forms returned.

14. In addition to these two systems, to ensure timely monitoring of the northern foreign longline fleet during the season, MAF requires each foreign vessel to make radio contact to report its position each week. Positions are updated more often if a vessel moves more than sixty nautical miles during the week. Vessels also report their weekly catch by species and weight at each radio contact.

IV. Data Management

15. Fisheries statistics are stored on a Prime P750 super-mini-computer at the Fisheries Research Centre. Official statistics are available on line via a national computer network, to all authorized fisheries staff within MAF. There are more than 250 users in at least 25 centres throughout the country.

16. Data management of all fisheries statistics is run by the FSU. The unit receives returns throughout the year for all fishing in the New Zealand EEZ. Figures 8 and 9 illustrate the general organization of the data management system.

17. Domestic statistics are processed as follows:-

- Upon receipt, returns are sorted by fishing method, i.e., form type, then checked by staff familiar with specific fisheries for obvious errors prior to machine encoding on magnetic tape. Encoded data are processed through error checking programs and any errors are corrected. The checking program is rerun until no errors are reported. At this point, returns are copied to master files which are the machine encoded equivalent of fishermen's returns. Master files can be used, but not edited, by any programmer who is recognized by the MAF computer system. Non-programmers who wish to examine the data on the master file can access it with a special interactive viewing program. This option, however, does not allow users to make summaries for themselves. To produce data summaries, two types of programs are regularly run. The first accesses the master file to create several standard updated summaries of landings by region and catches by fishing area for main fish species in a calendar year. In addition, summaries of species caught in each region by month and year, and species caught by each method by month and year are produced. The second type of program is used interactively in a question and answer format enabling users to summarise fishing return data according to their own specifications in report format or as input for further analysis.

- Logbooks from the foreign flag vessels are processed in a separate system. They are checked and encoded in the same way as domestic returns, but the data is not available to the network, and master files are only accessible to specialist users.
- Data gathered by the MAF fisheries scientists are also stored on computer but are not available to the network. These data are generally used only by scientific staff.
- In addition to catch and effort data, the FSU maintains individual vessel registration information on computer. Boat registration files contain details of all vessels, such as lengths, tonnages, owners, captain, and other data required for registration. Some of these data are available on request and some are included in summaries and data reports (e.g. vessel length related to catch).

V. Statistics for Domestic Fisheries

18. Data for the period 1974 to 1982 consist of landings by species, fisheries management region, month and fishing method. Effort data, however, was not encoded. Data summaries are available, but direct access otherwise is limited to specialist users.

19. From 1983 onward, all information given by fishermen on returns has been encoded and stored on master files. All data are available to specialist users. For non-programmers a comprehensive computer summary is available which includes catch and effort data for each management area. Extract programs allow users to choose any combinations of effort, fishing method, region, month, year, species, as well as size and type of vessel. Standard summaries are updated weekly and include landings by method in each landing region and catch by method in each fishing area.

VI. Statistics for Foreign Flag Vessels

20. Computer summaries are available for all seasons since 1980 and limited data are available for 1978 and 1979. No data were collected from foreign vessels on their fishing activity prior to 1978 when New Zealand extended its jurisdiction to 200 miles. The summaries include tables of monthly catch by species and management area, as well as summaries of catch and effort data by 1 grid. Specialist users can access all alongline data in the master file for analysis.

VII. Statistical Publications

21. Information released from MAF is commonly produced in the form of internal reports, occasional publications and in articles in popular magazines. Published statistics also occur in reports of other bodies that request data, but most reports are prepared for New Zealand internal purposes. These publications are available on request.

VIII. Problem Areas with Fisheries Statistics

22. The problems which have arisen in the development of a tuna fisheries database in New Zealand are common to many fisheries and to nations with limited resources for monitoring and enforcement.

23. Most fisheries in New Zealand are based on small owner-operator vessels less than 25m LOA which fish many species by several methods. To ensure routine return of catch and effort data we have found it necessary to develop a series of method specific reporting forms to provide a daily record of activity. A small operator may have to complete a variety of forms and so forms are kept simple and easy to complete. A straightforward form requires some sacrifice of detail, but results in a more dependable database of catch and effort. In addition, FSU staff and individual researchers routinely liaise with fishermen to encourage the return of accurate data. Lack of resources and limited space on vessels has prevented us from being able to run comprehensive observer programmes for routine verification of data supplied by fishermen.

24. One of the problems inherent in our system of fishing returns is their availability to other government departments. Conversations with fishermen lead us to suspect that under and over reporting biases have varied in importance between years. The perception of many New Zealand fishermen has been that if returns can be obtained for tax purposes then it is in their interest to neglect reporting the portion of their catch that they are able to sell for cash. These biases are usually easy to estimate and remain relatively constant between years. The proposed imposition of quotas even in unrelated fisheries however, may encourage fishermen to over report if they perceive that a quota based on fishing history is likely to be imposed.

25. In foreign licenced fisheries, vessels may catch several species but the method is the same throughout the season. These vessels are usually large and well staffed, and are able to provide greater detail on the fishing operation. Instructions on filling out the log, written in the mother tongue of the crew, ensure that we receive data that is as accurate as possible. Where possible, the log itself is also written in the crew's mother tongue.

26. Although the current system is satisfactory, we endeavour to improve data collection through liaison with fishermen to convince them of the usefulness of the data and to identify sources of bias.

The production and distribution of data summaries to fishermen appears to have improved the attitude of fishermen towards MAF and the completion of fishing returns. Verification of statistics rely on analysis of data from observer programs which at present are limited.

IX. Summary

27. Experience within New Zealand suggests that the following factors are essential for successful data collection:

- Forms should be simple and straightforward. Complex forms lead to incomplete returns, and may cause inaccuracies as fishermen estimate catch and effort at the end of a reporting period rather than at the end of each fishing operation.
- Handling of forms and summaries should be made by staff with experience in or knowledge of fishing. This ensures better quality of data, as errors are more obvious to staff if they are familiar with its source. It also facilitates liaison with fishermen at sea and at landing points.
- A complete library of data handling programs is essential to allow both specialist and non-specialist users to make use of the data. A commitment to program development ensures quality of data summaries and ease of access.
- Centralization of all returns and data handling has, in our experience, improved consistency in entry and use of data, and continuing contact with fishermen throughout the country compensates to some extent for the loss of local participation.

28. The double system by which catch and effort data is collected from all fishermen with more detailed data collected by scientists, allows accuracy and comprehensiveness for basic data, while at the same time affording detailed data where required.

Table 1

1983 Tuna catches in metric tonnes from the New Zealand EEZ compared with Southwest Pacific (FAO Area 81), total Pacific (FAO Areas 61, 67, 71, 77, 81 and 87) and world. Figures from Anon (1984a), Murray, et al (1984).
